

PROJECT 1

Administrating VPC and EC2 services by launching linux servers under Elastic load balancing rules under defined subnetworks with autoscaling method:

VPC:

- Open the AWS console→Navigate to VPC using the search bar→Create VPC→Name it for easy identification→Configure VPC CIDR block→Create VPC.

- Create 2 subnets in different availability zone for redundancy.

- Create internet gateway and attach it with the VPC to provide the VPC with internet access.

- The route table would be automatically created, if not create one → Edit route → Configure the route table and select the internet gateway and associate it with the subnets created.

EC2:

- Launch 2 instances by specifying the beloved VPC and create a security group for the instances and choose the subnet. (Make sure to enable auto assign IP for internet access.

- Create target group by selecting your VPC and registering both the subnets under the target.

- Create a load balancer by selecting your VPC and both of the subnets to balance the load between those.

- Launch template by specifying the AMI, instance type, security group which helps the auto scaling group to use or recreate your configuration.

- Create autoscaling group by selecting the appropriate template, VPC and both subnets and load balancer with target group.

- We can find that the health check has been done it has returned the healthy state.

- This project helps build a secure environment, ensures automatic traffic distribution and optimizes the costs.
